# Oxidation States, Hydrogenation, And Hydrogenolysis

from chapter(s) ir	n the recom	mended text
--------------------	-------------	-------------

#### A. Introduction

## **B. Oxidation States In Organic Chemistry**

Reduction is *addition* of electrons from the substrate, and *loss* from the reducing agent. Oxidation is e-addition from the oxidizing agent and loss from the substrate. more less less more  $CO_2$ g **HCOH** CH<sub>2</sub>Cl<sub>2</sub> CCI<sub>4</sub> HCCI<sub>3</sub>  $NH_2$ m 0 n d lowest oxidation state a, e, f, h one level higher c, i, l, o one more level higher b, j, k, n still another level higher g, m highest oxidation state

Cyclohexane is at a *higher* oxidation state than hexane.

#### C. Addition Of H<sub>2</sub>

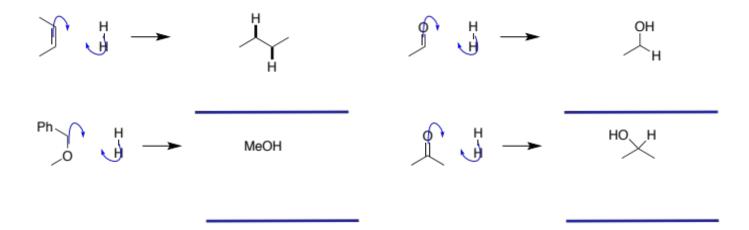

#### **Hydrogenation And Hydrogenolysis**

Hydrogenation involves addition of H<sub>2</sub> across an unsaturated bond without cleaving

Hydrogenolysis involves addition of H<sub>2</sub> across a single bond with cleavage.

Addition of hydrogen to an alkene or an aldehyde can be thought of as proceeding via: (i) homolytic cleavage of H<sub>2</sub>

Hydrogenolysis is closer to a *radical* mechanism, than a *ionic* one.

hydrogen adds to are inclined to *stabilize* a single electron.

hydrogenolysis of benzyl ethers favorable, because the *benzyl* radical is stabilized by resonance.

Aromatic aldehydes, ketones, and esters are  $\frac{more}{}$  easily hydrogenated than similar aliphatic

# D. Hydrogenation

$$\bigcirc$$

$$N \longrightarrow \frac{H_2}{\text{catalyst}}$$

Catalyst 
$$\frac{2 \, H_2}{}$$

$$\bigcirc$$

cis

cis

# E. Hydrogenolysis

Hydrogenolysis refers to addition across *single* bonds.

$$\begin{array}{c|c}
OH & OMe \\
\hline
 & H_2 \\
\hline
 & catalyst
\end{array}$$

$$\begin{array}{c|c}
 & H_2 \\
\hline
 & catalyst
\end{array}$$

Note: further hydrogenolysis of these products to alcohols is possible, and these may undergo hydrogenolysis to toluene.

$$\begin{array}{c|c} Ph & & & \\ \hline O & & \\ \hline CO_2Bn & & \\ \hline \end{array}$$

catalyst

does not reduce the base

It tends to be *harder* to remove benzyl groups from amines than from alcohols

benzyl group is connected to the oxygen of a carbamate, ie benzyloxycarbonyl or Cbz.

# **F. Double Bond Equivalents**

convert ethene and ethyne into ethane requires 1 and 2 molecules of H<sub>2</sub>

Conversion of benzene to hexane would require 4 molecules of H<sub>2</sub>

For hydrocarbons containing n carbon atoms, the DBE can be calculated

halogenated hydrocarbons containing n carbon atoms, can be calculated by replacing the halogen atoms DBEs of acetone and *cis*-1,2-cyclohexandiol are **1** and **1**, respectively.

may be ignored to calculate the DBE, eg acetone C<sub>3</sub>H<sub>6</sub>O may be considered to be C<sub>3</sub>H<sub>6</sub>. (*True*, check DBEs of 3-aminopropene and pyridine ar1 and 4

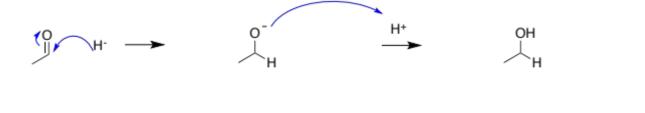

calculating the DBE, eg ethylamine  $C_2H_7N$  (DBE =0) may be considered to be  $C_3H_6$ . (*True*, check

They do not apply when calculating unsaturation between two atoms not including carbon but addition of O and S obviously changes oxidation state but does not change DBEs.

### **G. Hydridic Reductions**
